

Please prepare this task before your last lesson on 19th December. I will post a sample answer on Moncampus later. Please send me some feedback on how relevant this task is for you as I'm planning a similar task for your evaluation in the last lesson.

Thanks!

My email: Eileen.farrell@intervenant.igensia.com

Here is a scenario and task instructions designed to help you practise writing a technical documentation extract of approximately 350 words:

Scenario:

Your team has developed a new software module called "SmartDataAPI," an API designed to provide developers with intelligent data retrieval and filtering capabilities from a large-scale cloud database. It supports RESTful endpoints to retrieve data subsets based on custom filters and sorting parameters and returns results in JSON format. The API also includes built-in error handling with clear error codes and messages to assist developers in troubleshooting.

Task Instructions:

Write a technical documentation extract for the "SmartDataAPI" module. Your extract should include the following elements:

- Brief module overview describing the purpose and primary functionalities.
- Description of key API endpoints, including methods (GET, POST), expected inputs (parameters or query strings), and output format.
- Explanation of error handling mechanisms, including example error codes and messages.
- One example use case illustrating how a developer might call the API to retrieve filtered data.

Your documentation tone should be clear, concise, and aimed at fellow developers familiar with APIs but new to this specific module. Use technical terms appropriately but avoid unnecessary complexity. Structure your extract logically for readability.

The word count should be around 350 words.
